1. Метод решения дифференциальных уравнений

Необходимо найти решение дифференциального уравнения

$$\frac{dy}{dx} \equiv y' = f(x, y) ,$$

которое удовлетворяет условиям

$$y(0) = y_0$$
,

$$y(x) \in \mathbb{R}^n$$
.

Для объяснения метода рассмотрим функцию у, разложенную в ряд Тейлора.

$$y(x_0 + h) = y(x_0) + hy'(x_0) + \frac{1}{2}h^2y''(x_0) + \cdots$$

Чтобы удержать в ряде Тейлора член *n*-го порядка, необходимо вычислить *n*-ю производную зависимой переменной. Для получения второй производной в конечноразностной форме достаточно было знать наклон кривой на концах рассматриваемого интервала. Чтобы вычислить третью производную в конечно-разностном виде, необходимо иметь значения второй производной, по меньшей мере, в двух точках. Для этого необходимо дополнительно определить наклон кривой в некоторой промежуточной точке интервала *h*. Очевидно, чем выше порядок вычисляемой производной, тем больше дополнительных точек потребуется вычислить внутри интервала. Так как существует несколько способов расположения внутренних точек и выбора относительных весов для найденных производных, то метод Рунге-Кутта, в сущности, объединяет целое семейство методов решения дифференциальных уравнений.

Семейство явных методов Рунге-Кутта задаётся следующими формулами:

$$y_{n+1} = y_n + h \sum_{i=1}^{s} b_i k_i$$
,

где

$$k_1 = f(x_n, y_n),$$

$$k_2 = f(x_n + c_2 h, y_n + a_{21} h k_1),$$
...
$$k_s = f(x_n + c_s h, y_n + a_{s1} h k_1 + a_{s2} h k_2 + ... + a_{s,s-1} h k_{s-1})$$

Конкретный метод определяется числом s и коэффициентами b_i и a_{ij} . Эти коэффициенты часто упорядочивают в таблицу, называемую таблицей Бутчера:

Для коэффициентов метода Рунге-Кутта должны быть выполнены условия

$$\sum_{j=1}^{i-1} a_{ij} = \mathsf{c}_i$$
 для $i = 2, ..., s$.

Если требуется, чтобы метод имел порядок p, то следует также обеспечить условие

$$\bar{y}(h + x_0) - y(h + x_0) = O(h^{p+1}),$$

где $\bar{y}(h+x_0)$ — приближение, полученное по методу Рунге-Кутта. После многократного дифференцирования это условие преобразуется в систему полиномиальных уравнений относительно коэффициентов метода.

2. Метод решения систем дифференциальных уравнений

Необходимо решить дифференциальное уравнение второго порядка вида

$$\frac{d^2y}{dt^2} = g(t, y, \frac{dy}{dt})$$

Для этого введем замену

$$z = \frac{dy}{dt}$$

Уравнение можно будет представить в виде системы

$$\begin{cases} \frac{dy}{dt} = z, \\ \frac{dz}{dt} = g(t, y, z), \end{cases}$$

Начальные условия задачи Коши записываются в виде

$$y(t_0) = y_0$$

$$z(t_0) = z_0$$

Данную систему можно решить методом Рунге-Кутта, использую следующие формулы

$$\begin{cases} y_{n+1} = y_n + h(k_1 + 3k_2 + 3k_3 + k_4)/8 \\ z_{n+1} = z_n + h(q_1 + 3q_2 + 3q_3 + q_4)/8 \end{cases}$$

где

$$\begin{cases} k_1 = f_1(x_n, y_{n,z_n}) \\ q_1 = f_1(x_n, y_{n,z_n}) \\ k_2 = f_1(x_n + h/3, y_n + hk_1/3, z + hq_1/3) \\ q_2 = f_1(x_n + h/3, y_n + hk_1/3, z + hq_1/3) \\ k_3 = f_1(x_n + 2h/3, y_n - hk_1/3 + hk_2, z - hq_1/3 + hq_2) \\ q_3 = f_1(x_n + 2h/3, y_n - hk_1/3 + hk_2, z - hq_1/3 + hq_2) \\ k_4 = f_1(x_n + h, y_n + hk_1 - hk_2 + hk_3, z + hq_1 - hq_2 + hq_3) \\ q_4 = f_1(x_n + h, y_n + hk_1 - hk_2 + hk_3, z + hq_1 - hq_2 + hq_3) \end{cases}$$

3. Общая характеристика одношаговых методов

Всем одношаговым методам присущи определенные общие черты:

- 1) чтобы получить информацию в новой точке, надо иметь данные лишь в одной предыдущей точке;
- 2) в основе всех одношаговых методов лежит разложение функции в ряд Тейлора, в котором сохраняются члены, содержащие h в степени до k включительно. Целое число k называется порядком метода;
- 3) все одношаговые методы не требуют действительного вычисления производных, а вычисляется лишь сама функция в одной или нескольких промежуточных точках;
 - 4) свойство «самостартования» позволяет легко менять величину шага.

4. Постановка задачи

Требуется решить дифференциальное уравнение первого порядка

$$y' = \frac{2y}{xln(x)} + \frac{1}{x}, \qquad x \in [2, 3]$$
$$y(2) = -\ln(2)$$

И систему двух дифференциальных уравнений первого порядка

$$\begin{cases} y' = z^2 + x \\ z' = xy \end{cases}, \quad x \in [0, 1]$$
$$y(0) = 1$$
$$z(0) = 0.5$$

Для решения использовать метод Рунге-Кутта 2, 3 и 4-го порядков.

5. Метод решения поставленной задачи

Для проведения подсчетов была написана программа на языке программирования Руthon 3.9. В ней использовались библиотеки сторонних авторов, имеющие свободное распространение.

Непосредственно вычисления происходят в специальном модуле, который содержит функции, выполняющие подсчеты методом Рунге-Кутта 2, 3 и 4-го порядков.

Для задачи по нахождению решения одиночного ЛДУ они имеют следующий интерфейс:

В качестве аргументов функция принимает функцию из правой части дифференциального уравнения, значения x_0 и $y(x_0)$ задачи Коши, шаг и число отрезков, в узлах которых требуется вычислить численные значения решения задачи.

Для вычислений использовались следующие формулы:

2-го порядка точности:

$$k_1 = f(x_n, y_n),$$

 $k_2 = f(x_n + h, y_n + hk_1),$
 $y_{n+1} = y_n + h(k_1 + k_2)/2,$

3-го порядка точности:

$$k_1 = f(x_n, y_n),$$

$$k_2 = f(x_n + h/2, y_n + hk_1/2),$$

$$k_3 = f(x_n + h, y_n + hk_2/2),$$

$$y_{n+1} = y_n + h(k_1 + 4k_2 + k_3)/6,$$

4-го порядка точности:

$$k_1 = f(x_n, y_n),$$

$$k_2 = f(x_n + h/2, y_n + hk_1/2),$$

$$k_3 = f(x_n + h/2, y_n + hk_2/2),$$

$$k_4 = f(x_n + h, y_n + k_3),$$

$$y_{n+1} = y_n + h(k_1 + 2k_2 + 2k_3 + k_4)/6.$$

Для решения системы двух дифференциальных уравнений были написаны аналогичные функции, с тем отличаем, что правая часть уравнения задается в виде вектора двух функций, а задача Коши задается вектором из трех элементов $(x_0, y(x_0))$ и $z(x_0)$.

Представим задачу в виде

$$y'_1 = f_1(x, y_1, y_2),$$
 $y_1(0) = y_{1,0},$ $y_1(t) \in \mathbb{R}^n,$
 $y'_2 = f_2(x, y_1, y_2),$ $y_2(0) = y_{2,0},$ $y_2(t) \in \mathbb{R}^n.$

Тогда для подсчета используются следующие итерационные формулы:

$$y_{1,n+1} = y_{1,n} + h(k_1 + 3k_2 + 3k_3 + k_4)/8,$$

 $y_{2,n+1} = y_{2,n} + h(q_1 + 3q_2 + 3q_3 + q_4)/8,$

где:

$$k_{1} = f_{1}(x_{n}, y_{1,n}, y_{2,n}),$$

$$q_{1} = f_{2}(x_{n}, y_{1,n}, y_{2,n}),$$

$$k_{2} = f_{1}(x_{n} + h/3, y_{1,n} + hk_{1}/3, y_{2,n} + hq_{1}/3),$$

$$q_{2} = f_{2}(x_{n} + h/3, y_{1,n} + hk_{1}/3, y_{2,n} + hq_{1}/3),$$

$$k_{3} = f_{1}(x_{n} + 2h/3, y_{1,n} - hk_{1}/3 + hk_{2}, y_{2,n} - hq_{1}/3 + hq_{2}),$$

$$q_{3} = f_{2}(x_{n} + 2h/3, y_{1,n} - hk_{1}/3 + hk_{2}, y_{2,n} - hq_{1}/3 + hq_{2}),$$

$$k_{4} = f_{1}(x_{n} + h, y_{1,n} + hk_{1} - hk_{2} + hk_{3}, y_{2,n} + hq_{1} - hq_{2} + hq_{3}),$$

$$q_{4} = f_{2}(x_{n} + h, y_{1,n} + hk_{1} - hk_{2} + hk_{3}, y_{2,n} + hq_{1} - hq_{2} + hq_{3}),$$

Полный код функций, выполняющих метод Рунге-Кутта для ОДУ, представлен в Приложении G, для системы двух ОДУ в Приложении I.

Задание входных параметров представлено в Приложении D и Приложении H соответственно.

Код остальной программы для обеих задач идентичен и представлен в Приложении Е и F. Кроме того, весь код программы можно посмотреть в репозитории на GitHub (ссылка находится в списке литературы).

6. Анализ полученного решения

А. Решение ОДУ

Подробные таблицы с численным решением можно посмотреть в Приложениях А-С.

Рассмотрим график решения поставленной задачи методом Рунге-Кутта 2-го порядка с различным числом шагов.

Puc. 1

Puc. 2

Как можно заметить по Рис. 1, решение обладает большой точность, поэтому рассмотрим разницу на примере отдельной точки.

По Рис. 2 можем сделать вывод, что при увеличении шага вдвое конечная точность возрастает в 4 раза.

Аналогично можем заметить, что для метода 3-го порядка при уменьшении шага вдвое точность увеличивается в 8 раз (Рис. 4).

Puc. 3

Puc. 4

При использовании метода 4-го порядка сгущение сетки в 2 раза дает уменьшение погрешности в 16 раз (Рис. 6).

Puc. 5

Puc. 6

Сравним точность решения, которую дают методы Рунге-Кутта 2, 3 и 4-го порядка а так же решение, полученное с помощью библиотеки *питру*, а в частноести ее функции *odeint*.

Puc. 7

Как видим по Рис. 8, погрешность решения имеет огромную зависимоть от порядка используемого метода.

Puc. 8

В. Решение системы 2-х ОДУ

Puc. 9

Puc. 10

Puc. 11

Puc. 12

Puc. 13

Puc. 14

Puc. 15

Puc. 16

Puc. 17

Как можно заметить по Рис. 9 - Рис. 17, где изображены решения системы 2-х ОДУ (а именно, графики z(y)), наблюдаются все те же закономерности, что были при решении одного уравнения первого порядка.

Таблицы с численными решениям находятся в Приложениях Ј-М.

7. Заключение

Были произведены численные расчеты задачи Коши для ОДУ первого порядка и системы двух уравнений первого порядка. Для подсчетов на языке программирования Python 3.9 был написан модуль с функциями для математических вычислений, который впоследствии можно будет использовать для других задач, а также тестовая программа, решающая поставленную задачу с использованием этого модуля.

Решение было произведено с использованием метода Рунге-Кутта 2, 3 и 4-го порядков с различными шагами и была продемонстрирована разница в точности используемых методов.
